# Security and Privacy Considerations for the OASIS Security Assertion Markup Language (SAML)

**Document identifier:** cs-sstc-sec-consider-00

**Location:** <http://www.oasis-open.org/committees/security/docs>

**Publication date:** 19 April 2002

**Maturity level:** Committee Specification

**Send comments to:** If you are on the [security-services@lists.oasis-open.org](mailto:security-services@lists.oasis-open.org) list for committee members, send comments there. If you are not on that list, subscribe to the [security-services-comment@lists.oasis-open.org](mailto:security-services-comment@lists.oasis-open.org) list and send comments there. To subscribe, send an email message to [security-services-comment-request@lists.oasis-open.org](mailto:security-services-comment-request@lists.oasis-open.org) with the word "subscribe" as the body of the message.

# 90 1 Introduction

91 This non-normative document describes and analyzes the security and privacy properties of the OASIS  
92 Security Assertion Markup Language (SAML) defined in the core SAML specification [**SAMLCore**] and  
93 the SAML specification for bindings and profiles [**SAMLBind**]. The intent in this document is to provide  
94 input to the design of SAML, and to provide information to architects, implementors, and reviewers of  
95 SAML-based systems about the following:

- 96 • The threats, and thus security risks, to which a SAML-based system is subject
- 97 • The security risks the SAML architecture addresses, and how it does so
- 98 • The security risks it does not address
- 99 • Recommendations for countermeasures that mitigate those risks

100 Note that terms used in this document are as defined in the SAML glossary [**SAMLGloss**] unless  
101 otherwise noted.

102 The rest of this section describes the background and assumptions underlying the analysis in this  
103 document. Section 4 provides a high-level view of security techniques and technologies that should be  
104 used with SAML. Section 5 analyzes the specific risks inherent in the use of SAML.

## 105 2 Privacy

106 SAML includes the ability to make statements about the attributes and authorizations of authenticated  
107 entities. There are very many common situations in which the information carried in these statements is  
108 something that one or more of the parties to a communication would desire to keep accessible to as  
109 restricted as possible a set of entities. Statements of medical or financial attributes are simple examples  
110 of such cases.

111 Parties making statements, issuing assertions, conveying assertions, and consuming assertions must be  
112 aware of these potential privacy concerns and should attempt to address them in their implementations of  
113 SAML-aware systems.

### 114 2.1 Ensuring Confidentiality

115 Perhaps the most important aspect of ensuring privacy to parties in a SAML-enabled transaction is the  
116 ability to carry out the transaction with a guarantee of confidentiality. In other words, can the information  
117 in an assertion be conveyed from the issuer to the intended audience, and only the intended audience,  
118 without making it accessible to any other parties?

119 It is technically possible to convey information confidentially (a discussion of common methods for  
120 providing confidentiality occurs in the Security portion of the document in Section 4.2) and all parties to  
121 SAML-enabled transactions should analyze each of their steps in the interaction to ensure that they are  
122 taking the appropriate steps to ensure that information that should be kept confidential is actually being  
123 kept so.

124 It should also be noted that simply obscuring the contents of assertions may not be adequate protection  
125 of privacy. There are many cases where just the availability of the information that a given user (or IP  
126 address) was accessing a given service may constitute a breach of privacy (for example, an the  
127 information that a user accessed a medical testing facility for an assertion may be enough to breach  
128 privacy without knowing the contents of the assertion). Partial solutions to these problems can be  
129 provided by various techniques for anonymous interaction, outlined below.

### 130 2.2 Notes on Anonymity

#### 131 2.2.1 Definitions that Relate to Anonymity

132 There are no definitions of anonymity which are satisfying for all cases. Many definitions **[Anonymity]**  
133 deal with the simple case of a sender and a message, and discuss “anonymity” in terms of not being able  
134 to link a given sender to a sent message, or a message back to a sender.

135 And while that definition is adequate for the “one off” case, it ignores the aggregation of information that is  
136 possible over time based on behavior rather than an identifier.

137 Two notions which may be generally useful, and that relate to each other, can help define anonymity.

138 The first notion is to think about anonymity as being “within a set”, as in this comment from “Anonymity,  
139 Unobservability, and Pseudonymity” **[Anonymity]**:

140 “To enable anonymity of a subject, there always has to be an appropriate set of subjects with  
141 potentially the same attributes....

142 ...Anonymity is the stronger, the larger the respective anonymity set is and the more evenly  
143 distributed the sending or receiving, respectively, of the subjects within that set is”.

144 This notion is relevant to SAML because of the use of authorities. Even if a Subject is “anonymous”, that  
145 subject is still identifiable as a member of the set of Subjects within the domain of the relevant authority.

146 In the case where aggregating attributes of the user are provided, the set can become much smaller. For  
147 example, if the user is “anonymous” but has the attribute of “student in Course 6@mit.edu”. Certainly, the

148 number of Course 6 students is less than the number of MIT-affiliated persons which is less than the  
149 number of users everywhere.

150 Why does this matter? It matters because of the second notion. This idea is that non-anonymity leads to  
151 the ability of an adversary to harm expressed in Dingledine, Freedman, and Molnar's Freehaven  
152 document [**FreeHaven**]:

153 "Both anonymity and pseudonymity protect the privacy of the user's location and true name.  
154 Location refers to the actual physical connection to the system. The term "true name" was  
155 introduced by Vinge and popularized by May to refer to the legal identity of an individual.  
156 Knowing someone's true name or location allows you to hurt him or her."

157 This leads to a unification of the notion of anonymity within a set and ability to harm, from the same  
158 source [**FreeHaven**]:

159 "We might say that a system is partially anonymous if an adversary can only narrow down a  
160 search for a user to one of a 'set of suspects.' If the set is large enough, then it is impractical  
161 for an adversary to act as if any single suspect were guilty. On the other hand, when the set of  
162 suspects is small, mere suspicion may cause an adversary to take action against all of them."

163 SAML-enabled systems are limited to "partial anonymity" at best because of the use of authorities. An  
164 entity about whom an assertion is made is already identifiable as one of the pool of entities in a  
165 relationship with the issuing authority.

166 The limitations on anonymity can be a lot worse than simple authority association, depending on how  
167 identifiers are employed, as reuse of pseudonymous identifiers allows accretion of potentially identifying  
168 information (see Section 2.2.2). Additionally, users of SAML-enabled systems can also make the breach  
169 of anonymity worse by their actions (see Section 2.2.3).

## 170 **2.2.2 Pseudonymity and Anonymity**

171 Apart from legal identity, any identifier for a Subject can be considered a pseudonym. And even notions  
172 like "holder of key" can be considered as serving as the equivalent of a pseudonym in linking an action (or  
173 set of actions) to a Subject. Even a description such as "the user that just requested access to object XYZ  
174 at time 23:34" can serve as an equivalent of a pseudonym.

175 The point is, that with respect to "ability to harm" it makes no difference whether the user is described with  
176 an identifier or described by behavior (i.e. use of a key, or performance of an action).

177 What does make a difference is how often the particular equivalent of a pseudonym is used.

178 [3] gives a taxonomy of pseudonyms starting from personal pseudonyms (like nicknames) that are used  
179 all the time, through various types of role pseudonyms (e.g. Secretary of Defense), on to "one time use"  
180 pseudonyms.

181 Only one time use pseudonyms can give you anonymity (within SAML, consider this as "anonymity within  
182 a set").

183 The more often you use a given pseudonym, the more you reduce your anonymity and the more likely it is  
184 that you can be harmed. In other words re-use of a pseudonym allows additional potentially identifying  
185 information to be associated with the pseudonym. Over time this will lead to an accretion that can  
186 uniquely identify the identity associated with a pseudonym.

## 187 **2.2.3 Behavior and Anonymity**

188 As Joe Klein can attest, anonymity isn't all it is cracked up to be.

189 Klein is the "Anonymous" who authored Primary Colors. Despite his denials he was unmasked as the  
190 author by Don Foster, a Vassar professor who did a forensic analysis of the text of Primary Colors. Foster  
191 compared that text with texts from a list of suspects that he devised based on their knowledge bases and  
192 writing proclivities.

- 193 It was Klein's idiosyncratic usages that did him in (though apparently all authors have them).
- 194 The relevant point for SAML is that an "anonymous" user (even one that is never named) can be  
195 identified enough to be harmed by repeated unusual behavior. Here are some examples:
- 196 • A user who each Tuesday at 21:00 access a database that correlates finger lengths and life span  
197 starts to be non-anonymous. Depending on that user's other behavior, she or he may become  
198 "traceable" **[Pooling]** in that other "identifying" information may be able to be collected.
  - 199 • A user who routinely buys an usual set of products from a networked vending machine, certainly  
200 opens themselves to harm (by virtue of booby-trapping the products).

## 201 **2.2.4 Implications for Privacy**

202 Origin site authorities (i.e. Authentication Authorities and Attribute Authorities) can provide a degree of  
203 "partial anonymity" by employing one-time-use identifiers or keys (for the "holder of Key" case).

204 This anonymity is "partial" at best because the Subject is necessarily confined to the set of Subjects in a  
205 relationship with the Authority.

206 This set may be further reduced (thus further reducing anonymity) when aggregating attributes are used  
207 that further subset the user community at the origin site.

208 Users who truly care about anonymity must take care to disguise or avoid unusual patterns of behavior  
209 that could serve to "de-anonymize" them over time.

## 210 **3 Security**

### 211 **3.1 Background**

212 Communication between computer-based systems is subject to a variety of threats, and these threats  
213 carry some level of associated risk. The nature of the risk depends on a host of factors, including the  
214 nature of the communications, the nature of the communicating systems, the communication mediums,  
215 the communication environment, the end-system environments, and so on. Section 3 of the IETF  
216 guidelines on writing security considerations for RFCs [**Rescorla-Sec**] provides an overview of threats  
217 inherent in the Internet (and, by implication, intranets).

218 SAML is intended to aid deployers in establishing security contexts for application-level computer-based  
219 communications within or between security domains. By serving in this role, SAML addresses the  
220 “endpoint authentication” aspect (in part, at least) of communications security, and also the “unauthorized  
221 usage” aspect of systems security. Communications security is directly applicable to the design of SAML.  
222 Systems security is of interest mostly in the context of SAML’s threat models. Section 2 of the IETF  
223 guidelines gives an overview of communications security and systems security.

### 224 **3.2 Scope**

225 Some areas that impact broadly on the overall security of a system that uses SAML are explicitly outside  
226 the scope of SAML. While this document does not address these areas, they should always be  
227 considered when reviewing the security of a system. In particular, these issues are important, but beyond  
228 the scope of SAML:

- 229 • Initial authentication: SAML allows statements to be made about acts of authentication that have  
230 occurred, but includes no requirements or specifications for these acts of authentication.  
231 Consumers of authentication assertions should be wary of blindly trusting these assertions unless  
232 and until they know the basis on which they were made. Confidence in the assertions must never  
233 exceed the confidence that the asserting party has correctly arrived at the conclusions asserted.
- 234 • Trust Model: In many cases, the security of a SAML conversation will depend on the underlying  
235 trust model, which is typically based on a key management infrastructure (e.g., PKI, secret key).  
236 For example, SOAP messages secured by means of XML Signature [**XMLSig**] are secured only  
237 insofar as the keys used in the exchange can be trusted. Undetected compromised keys or  
238 revoked certificates, for example, could allow a breach of security. Even failure to require a  
239 certificate opens the door for impersonation attacks. PKI setup is not trivial and must be  
240 implemented correctly in order for layers built on top of it (such as parts of SAML) to be secure.

### 241 **3.3 SAML Threat Model**

242 The general Internet threat model described in the IETF guidelines for security considerations [**Rescorla-**  
243 **Sec**] is the basis for the SAML threat model. We assume here that the two or more endpoints of a SAML  
244 transaction are uncompromised, but that the attacker has complete control over the communications  
245 channel.

246 Additionally, due to the nature of SAML as multi-party authentication and authorization statement  
247 protocol, cases must be considered where one or more of the parties in a legitimate SAML transaction—  
248 who operate legitimately within their role for that transaction—attempt to use information gained from a  
249 previous transaction maliciously in a subsequent transaction.

250 In all cases, the local mechanisms that systems will use to decide whether or not to generate assertions  
251 are out of scope. Thus, threats arising from the details of the original login at an authentication authority,  
252 for example, are out of scope as well. If an authority issues a false assertion, then the threats arising  
253 from the consumption of that assertion by downstream systems are explicitly out of scope.

254 The direct consequence of such a scoping is that the security of a system based on assertions as inputs  
255 is only as good as the security of the system used to generate those assertions. When determining what  
256 issuers to trust, particularly in cases where the assertions will be used as inputs to authentication or  
257 authorization decisions, the risk of security compromises arising from the consumption of false but validly  
258 issued assertions is a large one. Trust policies between asserting and relying parties should always be  
259 written to include significant consideration of liability and implementations must be provide an audit trail.

## 260 **4 Security Techniques**

261 The following sections describe security techniques and various stock technologies available for their  
262 implementation in SAML deployments.

### 263 **4.1 Authentication**

264 Authentication here means the ability of a party to a transaction to determine the identity of the other party  
265 in the transaction. This authentication may be in one direction or it may be bilateral.

#### 266 **4.1.1 Active Session**

267 Non-persistent authentication is provided by the communications channel used to transport a SAML  
268 message. This authentication may be unilateral—from the session initiator to the receiver—or bilateral.  
269 The specific method will be determined by the communications protocol used. For instance, the use of a  
270 secure network protocol, such as RFC 2246 [**RFC2246**] or the IP Security Protocol [**IPsec**], provides the  
271 SAML message sender with the ability to authenticate the destination for the TCP/IP environment.

#### 272 **4.1.2 Message-Level**

273 XML Signature [**XMLSig**] provides a method of creating a persistent “authentication” that is tightly  
274 coupled to a document. This method does not independently guarantee that the sender of the message is  
275 in fact that signer (and indeed, in many cases where intermediaries are involved, this is explicitly not the  
276 case).

277 Any method that allows the persistent confirmation of the involvement of a uniquely resolvable entity with  
278 a given subset of an XML message is sufficient to meet this requirement.

### 279 **4.2 Confidentiality**

280 Confidentiality means that the contents of a message can be read only by the desired recipients and not  
281 anyone else who encounters the message while it is in transit.

#### 282 **4.2.1 In Transit**

283 Use of a secure network protocol such as RFC 2246 [**RFC2246**] or the IP Security Protocol [**IPsec**]  
284 provides transient confidentiality of a message as it is transferred between two nodes.

#### 285 **4.2.2 Message-Level**

286 XML Encryption [**XMLEnc**] is a draft specification for the selective encryption of XML documents. This  
287 encryption method provides persistent, selective confidentiality of elements within an XML message.

288 Until XML Encryption is an accepted standard, confidentiality may be implemented in transit (and not end-  
289 to-end) by reliance on transports that provide in-transit confidentiality (as described in Section 4.2.1  
290 above).

### 291 **4.3 Data Integrity**

292 Data integrity is the ability to confirm that a given message as received is unaltered from the version of  
293 the message that was sent.

### 294 **4.3.1 In Transit**

295 Use of a secure network protocol such as RFC 2246 [**RFC2246**] or the IP Security Protocol [**IPsec**] may  
296 be configured so as to provide for integrity check CRCs of the packets transmitted via the network  
297 connection.

### 298 **4.3.2 Message-Level**

299 XML Signature [**XMLSig**] provides a method of creating a persistent guarantee of the unaltered nature of  
300 a message that is tightly coupled to that message.

301 Any method that allows the persistent confirmation of the unaltered nature of a given subset of an XML  
302 message is sufficient to meet this requirement.

## 303 **4.4 Notes on Key Management**

304 Many points in this document will refer to the ability of systems to provide authentication, data integrity,  
305 and non-repudiation via various schemes involving digital signature and encryption. For all these  
306 schemes the security provided by the scheme is limited based on the key management systems that are  
307 in place. Some specific limitations are detailed below:

### 308 **4.4.1 Access to the Key**

309 It is assumed that if key-based systems are going to be used for authentication, data integrity, and non-  
310 repudiation, that security is in place to guarantee that access to the key is not available to inappropriate  
311 parties. For example, a digital signature created with Bob's private key is only proof of Bob's involvement  
312 to the extent that Bob is the only one with access to the key.

313 In general, access to keys should be kept to the minimum set of entities possible (particularly important  
314 for corporate or organizational keys, etc.) and should be protected with pass phrases and other means.  
315 Standard security precautions (don't write down the passphrase, don't leave a window with the key  
316 accessed open when you're away from a computer, etc.) apply.

### 317 **4.4.2 Binding of Identity to Key**

318 For a key-based system to be used for authentication there must be some trusted binding of identity to  
319 key. Verifying a digital signature on a document can determine if the document is unaltered since its  
320 signature, and that it was actually signed by a given key. However, this in no way confirms that the key  
321 used is actually the key of a specific individual.

322 This key-to-individual binding must be established. Common solutions include local directories that store  
323 both identifiers and key—which is simple to understand but difficult to maintain—or the use of certificates.

324 Certificates, which are in essence signed bindings of identity-to-key are a particularly powerful solution to  
325 the problem, but come with their own considerations. A set of trusted root Certifying Authorities (CAs)  
326 must be identified for each consumer of signatures—i.e. “Who do I trust to make statements of identity-to-  
327 key binding”. Verification of a signature then becomes a process of verifying first the signature (to  
328 determine that the signature was done by the key in question and that the message has not changed)  
329 and then verification of the certificate chain (to determine that the key is bound to the right identity).

330 Additionally, with certificates steps must be taken to ensure that the binding is currently valid—a  
331 certificate typically has a “lifetime” built into it, but if a key is compromised during the life of the certificate  
332 then the key-to-identity binding contained in the certificate becomes invalid while the certificate is still  
333 valid on its face. Also certificates often depend on associations that may end before their lifetime expires  
334 (for example certificates that should become invalid when someone changes employers, etc.) This  
335 problem is solved by Certificate Revocation Lists (CRLs) which are lists of certificates from a given CA  
336 that have been revoked since their issue. Another solution is the Online Certificate Status Protocol  
337 (OCSP) which defines a method for calling servers to ask about the current validity of a given certificate.

338 Some of this same functionality is incorporated into the higher levels of the XML Key Management  
339 Specification (XKMS) which allows requests to be made for “valid” keys.

340 A proper key management system is thus quite strong but very complex. Verifying a signature ends up  
341 being a three-stage process of verifying the document-to-key binding, then verifying the key-to-identity  
342 binding, then verifying the current validity of the key-to-document binding.

## 343 4.5 TLS/SSL Cipher Suites

344 The use of SSL 3.0 or TLS 1.0 (RFC 2246) [RFC2246] over HTTP is recommended at many places in  
345 this document. However TLS/SSL can be configured to use many different cipher suites, not all of which  
346 are adequate to provide “best practices” security. The following sections provide a brief description cipher  
347 suites and recommendations for cipher suite selection.

### 348 4.5.1 What Is a Cipher Suite?

349 **Note:** While references to the US Export restrictions are now obsolete, the  
350 constants naming the cipher suites have not changed. Thus,  
351 SSL\_DHE\_DSS\_EPORT\_WITH\_DES40\_CBC\_SHA is still a valid cipher suite  
352 identifier, and the explanation of the historical reasons for the inclusion of “EXPORT”  
353 has been left in place in the following summary.

354 A cipher suite combines four kinds of security features, and is given a name in the SSL protocol  
355 specification. Before data flows over a SSL connection, both ends attempt to negotiate a cipher suite.  
356 This lets them establish an appropriate quality of protection for their communications, within the  
357 constraints of the particular mechanism combinations which are available. The features associated with a  
358 cipher suite are:

- 359 1. The type of key exchange algorithm used. SSL defines many; the ones that provide server  
360 authentication are the most important ones, but anonymous key exchange is supported. (Note  
361 that anonymous key exchange algorithms are subject to “man in the middle” attacks, and are **not**  
362 **recommended** in the SAML context.) The “RSA” authenticated key exchange algorithm is  
363 currently the most interoperable algorithm. Another important key exchange algorithm is the  
364 authenticated Diffie-Hellman “DHE\_DSS” key exchange, which has no patent-related  
365 implementation constraints.<sup>1</sup>
- 366 2. Whether the key exchange algorithm is freely exportable from the United States of America.  
367 Exportable algorithms must use short (512-bit) public keys for key exchange and short (40-bit)  
368 symmetric keys for encryption. These keys are currently subject to breaking in an afternoon by a  
369 moderately well-equipped adversary.
- 370 3. The encryption algorithm used. The fastest option is the RC4 stream cipher; DES and variants  
371 (DES40, 3DES-EDE) are also supported in “cipher block chaining” (CBC) mode, as is null  
372 encryption (in some suites). (Null encryption does nothing; in such cases SSL is used only to  
373 authenticate and provide integrity protection. Cipher suites with null encryption do not provide  
374 confidentiality, and **should not be used** in cases where confidentiality is a requirement.)
- 375 4. The digest algorithm used for the Message Authentication Code. The choices are MD5 and  
376 SHA1.

377 For example, the cipher suite named SSL\_DHE\_DSS\_EXPORT\_WITH\_DES40\_CBC\_SHA uses SSL, an  
378 authenticated Diffie-Hellman key exchange (DHE\_DSS), is export grade (EXPORT), uses an exportable  
379 variant of the DES cipher (DES40\_CBC), and uses the SHA1 digest algorithm in its MAC (SHA).

---

<sup>1</sup> RSA patents have all expired; hence this issue is mostly historical.

380 A given implementation of SSL will support a particular set of cipher suites, and some subset of those will  
381 be enabled by default. Applications have a limited degree of control over the cipher suites that are used  
382 on their connections; they can enable or disable any of the supported cipher suites, but cannot change  
383 the cipher suites which are available.

#### 384 **4.5.2 Cipher Suite Recommendations**

385 The following cipher suites adequately meet requirements for confidentiality and message integrity, and  
386 can be configured to meet the authentication requirement as well (by forcing the presence of X.509v3  
387 certificates). They are also well supported in many client applications. Support of these suites is  
388 recommended:

- 389 • TLS\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA (when using TLS)
- 390 • SSL\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA (when using SSL)

391 However, the IETF is moving rapidly towards mandating the use of AES, which has both speed and  
392 strength advantages. Forward-looking systems would be wise as well to implement support for the AES  
393 cipher suites, such as:

- 394 • TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA

## 395 **5 SAML-Specific Security Considerations**

396 The following sections analyze the security risks in using and implementing SAML and describe  
397 countermeasures to mitigate the risks.

### 398 **5.1 SAML Assertions**

399 At the level of the SAML assertion itself, there is little to be said about security concerns—most concerns  
400 arise during communications in the request/response protocol, or during the attempt to use SAML by  
401 means of one of the bindings. However, one issue at the assertion level bears analysis: An assertion,  
402 once issued, is out of the control of the issuer.

403 This fact has a number of ramifications. For example, the issuer has no control over how long the  
404 assertion will be persisted in the systems of the consumer; nor does the issuer have control over the  
405 parties with whom the consumer will share the assertion information. These concerns are over and above  
406 concerns about a malicious attacker who can see the contents of assertions that pass over the wire  
407 unencrypted (or insufficiently encrypted).

408 While efforts have been made to address many of these issues within the SAML specification, nothing  
409 contained in the specification will erase the requirement for careful consideration of what to put in an  
410 assertion. At all times, issuers should consider the possible consequences if the information in the  
411 assertion is stored on a remote site, where it can be directly misused, or exposed to potential hackers, or  
412 possibly stored for more creatively fraudulent uses. Issuers should also consider the possibility that the  
413 information in the assertion could be shared with other parties, or even made public, either intentionally or  
414 inadvertently.

### 415 **5.2 SAML Protocol**

416 The following sections describe security considerations for the SAML request-response protocol itself,  
417 apart from any threats arising from use of a particular protocol binding.

#### 418 **5.2.1 Denial of Service**

419 The SAML protocol is susceptible to a denial of service (DOS) attack. Handling a SAML request is  
420 potentially a very expensive operation, including parsing the request message (typically involving  
421 construction of a DOM tree), database/assertion store lookup (potentially on an unindexed key),  
422 construction of a response message, and potentially one or more digital signature operations. Thus, the  
423 effort required by an attacker generating requests is much lower than the effort needed to handle those  
424 requests.

##### 425 **5.2.1.1 Requiring Client Authentication at a Lower Level**

426 Requiring clients to authenticate at some level below the SAML protocol level (for example, using the  
427 SOAP over HTTP binding, with HTTP over TLS/SSL, and with a requirement for client-side certificates  
428 that have a trusted Certificate Authority at their root) will provide traceability in the case of a DOS attack.

429 If the authentication is used only to provide traceability then this does not in itself prevent the attack from  
430 occurring, but does function as a deterrent.

431 If the authentication is coupled with some access control system, then DOS attacks from non-insiders is  
432 effectively blocked. (Note that it is possible that overloading the client-authentication scheme could still  
433 function as a denial-of-service attack on the SAML service, but that this attack needs to be dealt with in  
434 the context of the client authentication scheme chosen.)

435 Whatever system of client authentication is used, it should provide the ability to resolve a unique  
436 originator for each request, and should not be subject to forgery. (For example, in the traceability-only  
437 case, logging the IP address is insufficient since this information can easily be spoofed.)

### 438 **5.2.1.2 Requiring Signed Requests**

439 In addition to the benefits gained from client authentication discussed in Section 5.2.1.1, requiring a  
440 signed request also lessens the order of the asymmetry between the work done by requester and  
441 responder. The additional work required of the responder to verify the signature is a relatively small  
442 percentage of the total work required of the responder, while the process of calculating the digital  
443 signature represents a relatively large amount of work for the requester. Narrowing this asymmetry  
444 decreases the risk associated with a DOS attack.

445 Note however that an attacker can theoretically capture a signed message and then replay it continually,  
446 getting around this requirement. This situation can be avoided by requiring the use of the XML Signature  
447 element `<ds:SignatureProperties>` containing a timestamp; the timestamp can then be used to  
448 determine if the signature is recent. In this case, the narrower the window of time after issue that a  
449 signature is treated as valid, the higher security you have against replay denial of service attacks.

### 450 **5.2.1.3 Restricting Access to the Interaction URL**

451 Limiting the ability to issue a request to a SAML service at a very low level to a set of known parties  
452 drastically reduces the risk of a DOS attack. In this case, only attacks originating from within the finite set  
453 of known parties are possible, greatly decreasing exposure both to potentially malicious clients and to  
454 DOS attacks using compromised machines as zombies.

455 There are many possible methods of limiting access, including placing the SAML responder inside a  
456 secured intranet, implementing access rules at the router level, etc.

## 457 **5.3 SAML Protocol Bindings**

458 The security considerations in the design of the SAML request-response protocol depend to a large  
459 extent on the particular protocol binding (as defined in the SAML bindings specification [**SAMBind**]) that  
460 is used. Currently the only binding sanctioned by the OASIS SAML Committee is the SOAP binding.

### 461 **5.3.1 SOAP Binding**

462 Since the SAML SOAP binding requires no authentication and has no requirements for either in-transit  
463 confidentiality or message integrity, it is open to a wide variety of common attacks, which are detailed in  
464 the following sections. General considerations are discussed separately from considerations related to  
465 the SOAP-over-HTTP case.

#### 466 **5.3.1.1 Eavesdropping**

467 Since there is no in-transit confidentiality requirement, it is possible that an eavesdropping party could  
468 acquire both the SOAP message containing a request and the SOAP message containing the  
469 corresponding response. This acquisition exposes both the nature of the request and the details of the  
470 response, possibly including one or more assertions.

471 Exposure of the details of the request will in some cases weaken the security of the requesting party by  
472 revealing details of what kinds of assertions it requires, or from whom those assertions are requested. For  
473 example, if an eavesdropper can determine that site X is frequently requesting authentication assertions  
474 with a given confirmation method from site Y, he may be able to use this information to aid in the  
475 compromise of site X.

476 Similarly, eavesdropping on a series of authorization queries could create a "map" of resources that are  
477 under the control of a given authorization authority.

478 Additionally, in some cases exposure of the request itself could constitute a violation of privacy. For  
479 example, eavesdropping on a query and its response may expose that a given user is active on the  
480 querying site, which could be information that should not be divulged in cases such as medical  
481 information sites, political sites, and so on. Also the details of any assertions carried in the response may  
482 be information that should be kept confidential. This is particularly true for responses containing attribute

483 assertions; if these attributes represent information that should not be available to entities not party to the  
484 transaction (credit ratings, medical attributes, and so on), then the risk from eavesdropping is high.

485 In cases where any of these risks is a concern, the countermeasure for eavesdropping attacks is to  
486 provide some form of in-transit message confidentiality. For SOAP messages, this confidentiality can be  
487 enforced either at the SOAP level or at the SOAP transport level (or some level below it).

488 Adding in-transit confidentiality at the SOAP level means constructing the SOAP message such that,  
489 regardless of SOAP transport, no one but the intended party will be able to access the message. The  
490 general solution to this problem is likely to be XML Encryption [XMLEnc]. This draft specification allows  
491 encryption of the SOAP message itself, which eliminates the risk of eavesdropping unless the key used in  
492 the encryption has been compromised. Alternatively, until XML Encryption is widely supported, deployers  
493 will need to depend on the SOAP transport layer, or a layer beneath it, to provide in-transit confidentiality.

494 The details of how to provide this confidentiality depend on the specific SOAP transport chosen. Using  
495 HTTP over TLS/SSL (described further in Section 5.3.2) is one method. Other transports will necessitate  
496 other in-transit confidentiality techniques; for example, an SMTP transport might use S/MIME.

497 In some cases, a layer beneath the SOAP transport might provide the required in-transit confidentiality.  
498 For example, if the request-response interaction is carried out over an IPsec tunnel, then adequate in-  
499 transit confidentiality may be provided by the tunnel itself.

### 500 **5.3.1.2 Replay**

501 There is little vulnerability to replay attacks at the level of the SOAP binding. Replay is more of an issue in  
502 the various profiles. The primary concern about replay at the SOAP binding level is the potential for use of  
503 replay as a denial-of-service attack method.

504 In general, the best way to prevent replay attacks is to prevent the message capture in the first place.  
505 Some of the transport-level schemes used to provide in-transit confidentiality will accomplish this goal.  
506 For example, if the SAML request-response conversation occurs over SOAP on HTTP/TLS, third parties  
507 are prevented from capturing the messages.

508 Note that since the potential replayer does not need to understand the message to replay it, schemes  
509 such as XML Encryption do not provide protection against replay. If an attacker can capture a SAML  
510 request that has been signed by the requester and encrypted to the responder, then the attacker can  
511 replay that request at any time without needing to be able to undo the encryption. This is a particular  
512 issue since the SAML request does not include information about the issue time of the request, thus  
513 making it difficult to determine if replay is occurring. The only recourse is to design systems that use the  
514 unique key of the request (its `RequestID`) to determine if this is a replay request or not.

515 Additional threats from the replay attack include cases where a “charge per request” model is in place.  
516 Replay could be used to run up large charges on a given account.

517 Similarly models where a client is allocated (or purchases) a fixed number of interactions with a system,  
518 the replay attack could exhaust these uses unless the issuer is careful to keep track of the unique key of  
519 each Request.

### 520 **5.3.1.3 Message Insertion**

521 The message insertion attack for the SOAP binding amounts to the creation of a request. The ability to  
522 make a request is not a threat at the SOAP binding level.

### 523 **5.3.1.4 Message Deletion**

524 The message deletion attack would either prevent a request from reaching a responder, or would prevent  
525 the response from reaching the requestor.

526 In either case, the SOAP binding does not address this threat. The SOAP protocol itself, and the  
527 transports beneath it, may provide some information depending on how the message deletion is  
528 accomplished.

529 Examples of reliable messaging systems that attenuate this risk include reliable HTTP (HTTPR) [HTTPR]  
530 at the transport layer and the use of reliable messaging extensions in SOAP such as Microsoft's SRMP  
531 for MSMQ [SRMPres].

### 532 **5.3.1.5 Message Modification**

533 Message modification is a threat to the SOAP binding in both directions.

534 Modification of the request to alter the details of the request can result in significantly different results  
535 being returned, which in turn can be used by a clever attacker to compromise systems depending on the  
536 assertions returned. For example, altering the list of requested attributes in the  
537 <AttributeDesignator> elements could produce results leading to compromise or rejection of the  
538 request by the responder.

539 Modification of the request to alter the apparent issuer of the request could result in denial of service or  
540 incorrect routing of the response. This alteration would need to occur below the SAML level and is thus  
541 out of scope.

542 Modification of the response to alter the details of the assertions therein could result in vast degrees of  
543 compromise. The simple examples of altering details of an authentication or an authorization decision  
544 could lead to very serious security breaches.

545 In order to address these potential threats, a system that guarantees in-transit message integrity must be  
546 used. The SAML protocol and the SOAP binding neither require nor forbid the deployment of systems that  
547 guarantee in-transit message integrity, but due to this large threat, it is **highly recommended** that such a  
548 system be used. At the SOAP binding level, this can be accomplished by digitally signing requests and  
549 responses with a system such as XML Signature [XMLSig]. The SAML specification allows for such  
550 signatures see the SAML Core Specification [SAMLCore] Section 5 for further information.

551 If messages are digitally signed (with a sensible key management infrastructure, see Section 4.4) then  
552 the recipient has a guarantee that the message has not be altered in transit, unless the key used has  
553 been compromised.

554 The goal of in-transit message integrity can also be accomplished at a lower level by using a SOAP  
555 transport that provides the property of guaranteed integrity, or is based on a protocol that provides such a  
556 property. SOAP over HTTP over TLS/SSL is a transport that would provide such a guarantee.

557 Encryption alone does not provide this protection, as even if the intercepted message could not be altered  
558 per se, it could be replaced with a newly created one.

### 559 **5.3.1.6 Man-in-the-Middle**

560 The SOAP binding is susceptible to man-in-the-middle (MITM) attacks. In order to prevent malicious  
561 entities from operating as a man in the middle (with all the perils discussed in both the eavesdropping and  
562 message modification), some sort of bilateral authentication is required.

563 A bilateral authentication system would allow both parties to determine that what they are seeing in a  
564 conversation actually came from the other party to the conversation.

565 At the SOAP binding level, this goal could also be accomplished by digitally signing both requests and  
566 responses (with all the caveats discussed in Section 5.3.1.5 above). This method does not prevent an  
567 eavesdropper from sitting in the middle and forwarding both ways, but he is prevented from altering the  
568 conversation in any way without being detected.

569 Since many applications of SOAP do not use sessions, this sort of authentication of author (as opposed  
570 to authentication of sender) may need to be combined with information from the transport layer to confirm

571 that the sender and the author are the same party in order to prevent a weaker form of “MITM as  
572 eavesdropper”.

573 Another implementation would depend on a SOAP transport that provides, or is implemented on a lower  
574 layer that provides, bilateral authentication. The example of this is again SOAP over HTTP over TLS/SSL  
575 with both server- and client-side certificates required.

576 Additionally, the validity interval of the assertions returned functions as an adjustment on the degree of  
577 risk from MITM attacks. The shorter the valid window of the assertion, the less damage can be done if it is  
578 intercepted.

### 579 **5.3.2 Specifics of SOAP over HTTP**

580 Since the SOAP binding requires that conformant applications support HTTP over TLS/SSL with a  
581 number of different bilateral authentication methods such as Basic over server-side SSL, certificate-  
582 backed authentication over server-side SSL, these methods are always available to mitigate threats in  
583 cases where other lower-level systems are not available and the above listed attacks are considered  
584 significant threats.

585 This does not mean that use of HTTP over TLS with some form of bilateral authentication is mandatory.. If  
586 an acceptable level of protection from the various risks can be arrived at through other means (for  
587 example, by an IPsec tunnel), full TLS with certificates is not required. However, in the majority of cases  
588 for SOAP over HTTP, using HTTP over TLS with bilateral authentication will be the appropriate choice.

589 Note, however, that the use of transport-level security (such as the SSL or TLS protocols under HTTP)  
590 only provides confidentiality and/or integrity and/or authentication for “one hop”. For models where there  
591 may be intermediaries, or the assertions in question need to live over more than one hop, the use of  
592 HTTP with TLS/SSL does not provide adequate security.

## 593 **5.4 Profiles for SAML**

594 The SAML bindings specification [**SAMLBind**] in addition defines profiles for SAML, which are sets of  
595 rules describing how to embed and extract SAML assertions into a framework or protocol. Currently there  
596 are two profiles for SAML that are sanctioned by the OASIS SAML Committee:

- 597 • Two web browser-based profiles that support single sign-on (SSO):
  - 598 ○ The browser/artifact profile for SAML
  - 599 ○ The browser/POST profile for SAML

### 600 **5.4.1 Web Browser-Based Profiles**

601 The following sections describe security considerations that are common to the browser/artifact and  
602 browser/POST profiles for SAML.

603 Note that user authentication at the source site is explicitly out of scope, as are all issues that arise from  
604 it. The key notion is that the source system entity must be able to ascertain that it is the same  
605 authenticated client system entity that it is interacting with in the next interaction step. One way to  
606 accomplish this is for these initial steps to be performed using TLS as a session layer underneath the  
607 protocol being used for this initial interaction (likely HTTP).

#### 608 **5.4.1.1 Eavesdropping**

609 The possibility of eavesdropping exists in all web browser cases. In cases where confidentiality is  
610 required (bearing in mind that any assertion that is not sent securely, along with the requests associated  
611 with it, is available to the malicious eavesdropper), HTTP traffic needs to take place over a transport that  
612 ensures confidentiality. HTTP over TLS/SSL [**RFC2246**] and the IP Security Protocol [**IPsec**] meet this  
613 requirement.

614 The following sections provide more detail on the eavesdropping threat.

#### 615 **5.4.1.1.1 Theft of the User Authentication Information**

616 In the case where the subject authenticates to the source site by revealing authentication information, for  
617 example, in the form of a password, theft of the authentication information will enable an adversary to  
618 impersonate the subject.

619 In order to avoid this problem, the connection between the subject's browser and the source site must  
620 implement a confidentiality safeguard. In addition, steps must be taken by either the subject or the  
621 destination site to ensure that the source site is genuinely the expected and trusted source site before  
622 revealing the authentication information. Using HTTP over TLS can be used to address this concern.

#### 623 **5.4.1.1.2 Theft of the Bearer Token**

624 In the case where the authentication assertion contains the assertion bearer authentication protocol  
625 identifier, theft of the artifact will enable an adversary to impersonate the subject.

626 Each of the following methods decreases the likelihood of this happening:

- 627 • The destination site implements a confidentiality safeguard on its connection with the subject's  
628 browser.
- 629 • The subject or destination site ensures (out of band) that the source site implements a  
630 confidentiality safeguard on its connection with the subject's browser.
- 631 • The destination site verifies that the subject's browser was directly redirected by a source site that  
632 directly authenticated the subject.
- 633 • The source site refuses to respond to more than one request for an assertion corresponding to  
634 the same assertion ID.
- 635 • If the assertion contains a condition element of type AudienceRestrictionConditionType that  
636 identifies a specific domain, then the destination site verifies that it is a member of that domain.
- 637 • The connection between the destination site and the source site, over which the assertion ID is  
638 passed, is implemented with a confidentiality safeguard.
- 639 • The destination site, in its communication with the source site, over which the assertion ID is  
640 passed, must verify that the source site is genuinely the expected and trusted source site.

#### 641 **5.4.1.2 Replay**

642 The possibility of a replay attack exists for this set of profiles. A replay attack can be used either to  
643 attempt to deny service or to retrieve information fraudulently. The specific countermeasures depend on  
644 which specific profile is being used, and thus are discussed in Sections 5.4.2.1 and 5.4.3.1.

#### 645 **5.4.1.3 Message Insertion**

646 Message insertion attacks are not a general threat in this set of profiles.

#### 647 **5.4.1.4 Message Deletion**

648 Deleting a message during any step of the interactions between the browser, SAML assertion issuer, and  
649 SAML assertion consumer will cause the interaction to fail. It results in a denial of some service but does  
650 not increase the exposure of any information.

651 The SAML bindings and profiles specification provides no countermeasures for message deletion.

652 **5.4.1.5 Message Modification**

653 The possibility of alteration of the messages in the stream exists for this set of profiles. Some potential  
654 undesirable results are as follows:

- 655 • Alteration of the initial request can result in rejection at the SAML issuer, or creation of an artifact  
656 targeted at a different resource than the one requested
- 657 • Alteration of the artifact can result in denial of service at the SAML consumer.
- 658 • Alteration of the assertions themselves while in transit could result in all kinds of bad results (if  
659 they are unsigned) or denial of service (if they are signed and the consumer rejects them).

660 To avoid message modification, the traffic needs to be transported by means of a system that guarantees  
661 message integrity from endpoint to endpoint.

662 For the web browser-based profiles, the recommended method of providing message integrity in transit is  
663 the use of HTTP over TLS/SSL with a cipher suite that provides data integrity checking.

664 **5.4.1.6 Man-in-the-Middle**

665 Man-in-the-middle attacks are particularly pernicious for this set of profiles. The MITM can relay requests,  
666 capture the returned assertion (or artifact), and relay back a false one. Then the original user cannot  
667 access the resource in question, but the MITM can do so using the captured resource.

668 Preventing this threat requires a number of countermeasures. First, using a system that provides strong  
669 bilateral authentication will make it much more difficult for a MITM to insert himself into the conversation.

670 However the possibility still exists of a MITM who is purely acting as a bidirectional port forwarder, and  
671 eavesdropping on the information with the intent to capture the returned assertion or handler (and  
672 possibly alter the final return to the requester). Putting a confidentiality system in place will prevent  
673 eavesdropping. Putting a data integrity system in place will prevent alteration of the message during port  
674 forwarding.

675 For this set of profiles, all the requirements of strong bilateral session authentication, confidentiality, and  
676 data integrity can be met by the use of HTTP over TLS/SSL if the TLS/SSL layer uses an appropriate  
677 cipher suite (strong enough encryption to provide confidentiality, and supporting data integrity) and  
678 requires X509v3 certificates for authentication.

679 **5.4.2 Browser/Artifact Profile**

680 Many specific threats and counter-measures for the Browser/Artifact profile are documented normatively  
681 in the SAML bindings specification [**SAMLBind**] Section 4.1.1.7. Additional non-normative comments are  
682 included below.

683 **5.4.2.1 Replay**

684 The threat of replay as a reuse of an artifact is addressed by the requirement that each artifact is a one-  
685 time-use item. Systems should track cases where multiple requests are made referencing the same  
686 artifact, as this situation may represent intrusion attempts.

687 The threat of replay on the original request that results in the assertion generation is not addressed by  
688 SAML, but should be mitigated by the original authentication process.

689 **5.4.3 Browser/POST Profile**

690 Many specific threats and counter-measures for the Browser/POST profile are documented normatively in  
691 the SAML bindings specification [**SAMLBind**] Section 4.1.2.5. Additional non-normative comments are  
692 included below.

693 **5.4.3.1 Replay**

694 Replay attacks amount to resubmission of the form in order to access a protected resource fraudulently.  
695 The profile mandates that the assertions transferred have the one-use property at the destination site,  
696 preventing replay attacks from succeeding.

## 743 **Appendix A. Acknowledgments**

744 The editors would like to acknowledge the contributions of the OASIS SAML Technical Committee, whose  
745 voting members at the time of publication were:

- 746 • Allen Rogers, Authentica
- 747 • Irving Reid, Baltimore Technologies
- 748 • Krishna Sankar, Cisco Systems
- 749 • Simon Godik, Crosslogix
- 750 • Gilbert Pilz, E2open
- 751 • Hal Lockhart, Entegriety
- 752 • Carlisle Adams, Entrust
- 753 • Don Flinn, Hitachi
- 754 • Joe Pato, Hewlett-Packard (co-chair)
- 755 • Jason Rouault, Hewlett-Packard
- 756 • Marc Chanliau, Netegrity
- 757 • Chris McLaren, Netegrity
- 758 • Prateek Mishra, Netegrity
- 759 • Charles Knouse, Oblix
- 760 • Steve Anderson, OpenNetwork
- 761 • Rob Philpott, RSA Security
- 762 • Jahan Moreh, Sigaba
- 763 • Bhavna Bhatnagar, Sun Microsystems
- 764 • Jeff Hodges, Sun Microsystems (co-chair)
- 765 • Eve Maler, Sun Microsystems (former chair)
- 766 • Aravindan Ranganathan, Sun Microsystems
- 767 • Emily Xu, Sun Microsystems
- 768 • Bob Morgan, University of Washington
- 769 • Phillip Hallam-Baker, VeriSign

## 770 **Appendix B. Notices**

771 OASIS takes no position regarding the validity or scope of any intellectual property or other rights that  
772 might be claimed to pertain to the implementation or use of the technology described in this document or  
773 the extent to which any license under such rights might or might not be available; neither does it  
774 represent that it has made any effort to identify any such rights. Information on OASIS's procedures with  
775 respect to rights in OASIS specifications can be found at the OASIS website. Copies of claims of rights  
776 made available for publication and any assurances of licenses to be made available, or the result of an  
777 attempt made to obtain a general license or permission for the use of such proprietary rights by  
778 implementors or users of this specification, can be obtained from the OASIS Executive Director.

779 OASIS invites any interested party to bring to its attention any copyrights, patents or patent applications,  
780 or other proprietary rights which may cover technology that may be required to implement this  
781 specification. Please address the information to the OASIS Executive Director.

782 Copyright © The Organization for the Advancement of Structured Information Standards [OASIS] 2001.  
783 All Rights Reserved.

784 This document and translations of it may be copied and furnished to others, and derivative works that  
785 comment on or otherwise explain it or assist in its implementation may be prepared, copied, published  
786 and distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice  
787 and this paragraph are included on all such copies and derivative works. However, this document itself  
788 may not be modified in any way, such as by removing the copyright notice or references to OASIS,  
789 except as needed for the purpose of developing OASIS specifications, in which case the procedures for  
790 copyrights defined in the OASIS Intellectual Property Rights document must be followed, or as required to  
791 translate it into languages other than English.

792 The limited permissions granted above are perpetual and will not be revoked by OASIS or its successors  
793 or assigns.

794 This document and the information contained herein is provided on an "AS IS" basis and OASIS  
795 DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY  
796 WARRANTY THAT THE USE OF THE INFORMATION HEREIN WILL NOT INFRINGE ANY RIGHTS OR  
797 ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.
